  - **Summary**

## BASICS OF FLUORESCENCE LIFETIME

# Luminescence

(from Latin *lumen* – light) emission of ultraviolet, visible or infrared photons from electronically excited specimen.

Eilhardt Wiedemann, 1888: “all those phenomena of light which are not solely conditioned by the rise in temperature”.

## 1. ORGANIC COMPOUNDS

AROMATIC HYDROCARBONS  
FLUORESCEIN  
RHODAMINES  
COUMARINES  
AMINOACIDS

## 2. ORGANOMETALLIC COMPOUNDS

RUTHENIUM COMPLEXES  
COMPLEXES WITH LANTHANIDES

## 3. INORGANIC COMPOUNDS

URANYL ION ( $\text{UO}_2^+$ )  
LANTHANIDE IONS ( $\text{Eu}^{3+}$ ,  $\text{Tb}^{3+}$ , ETC.)  
DOPED GLASSES (Nd, Mn, Ce, ETC.)  
CRYSTALS (ZnS, CDS, ZnSe, ETC.)

phosphorescence

**Radioluminescence**

**Cathodoluminescence**

**Electroluminescence**

**Thermoluminescence**

**Chemiluminescence**

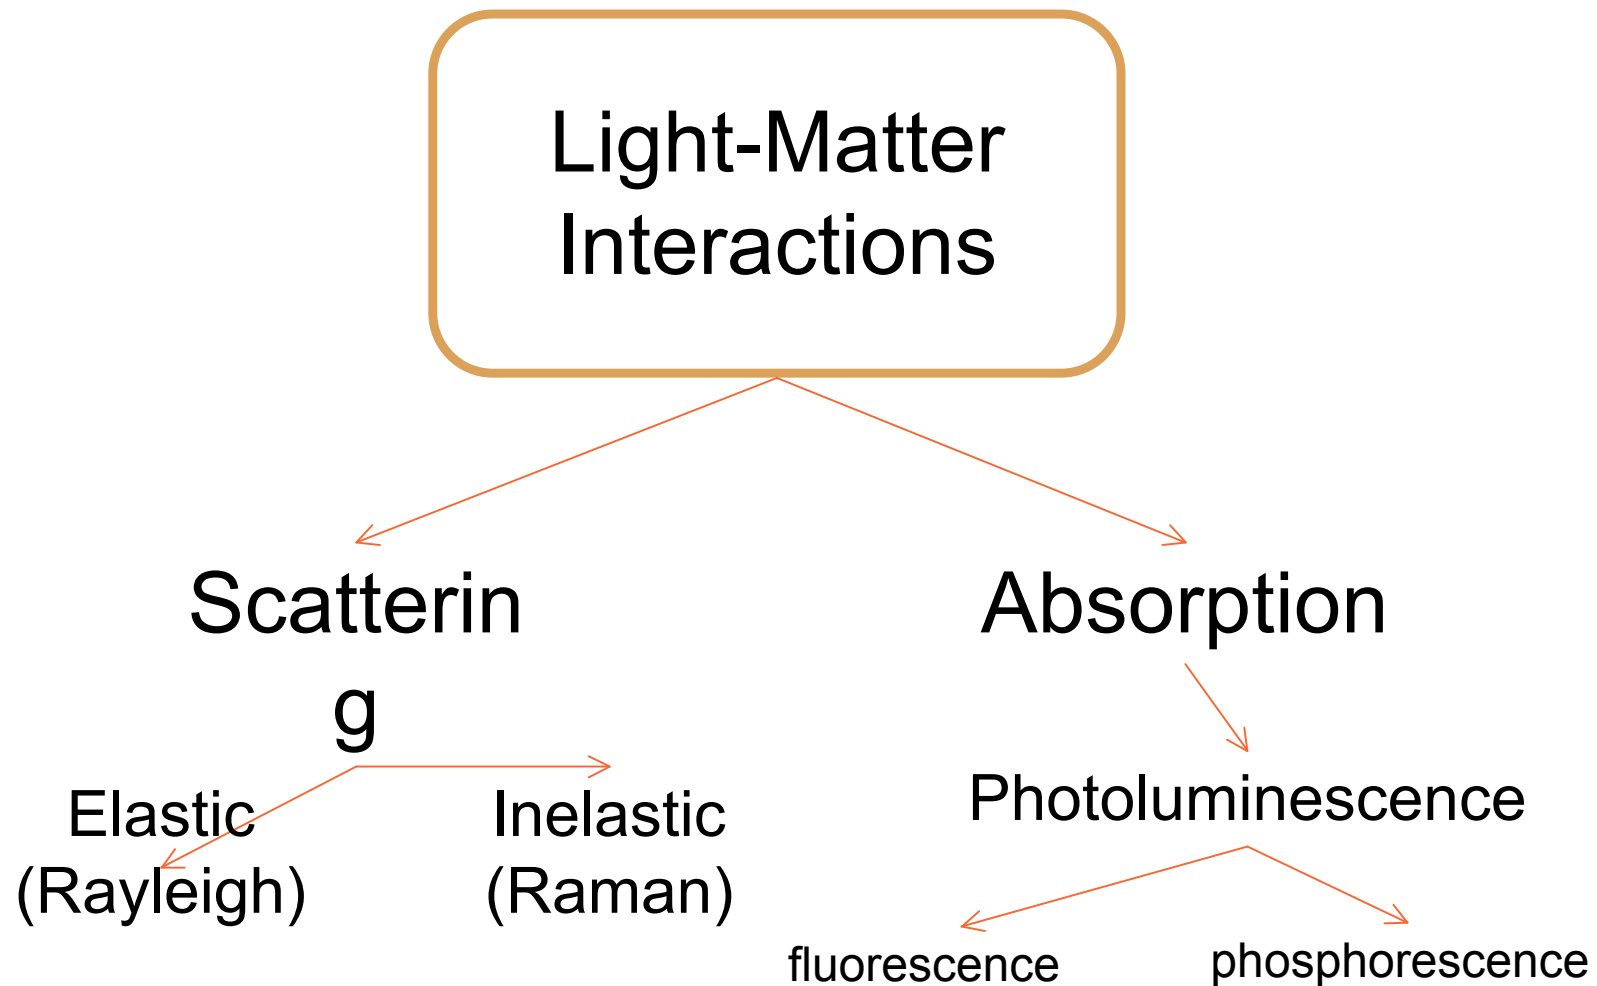

**Bioluminescence**

**Triboluminescence**

**Sonoluminescence**

# Light-Matter Interactions

# Ethymology

First observed in 1565 by Nicholas Monardes in the infusion of *Lignum Nephriticum*. Repeated by Boyle and Newton.  
The term introduced by Sir George Gabriel Stokes in 1842.  
Blue light observed from quinine similar to that seen from fluorspar.

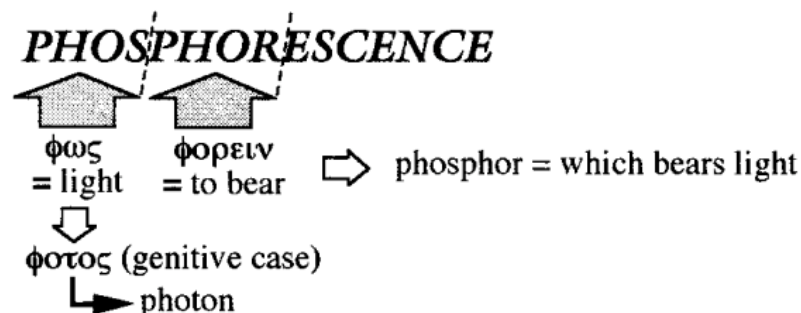

Spars – in the 18<sup>th</sup> century transparent stones, easily melted.

Fluor – (fluere – liquid in Latin).

Fluorspars are not fluorescent! Presence of Europium ions.

First observed in 1608 in the calcinated Bolognian Phosphor.

# Fluorescence properties

## Spectra

Stoke's shift

Mirror image rule

## Fluorescence brightness

Quantum yield – number of emitted photons relative to the numbers of absorbed photons

$$Q = \frac{\Gamma}{\Gamma + k_{nr}}$$

# Perrin-Jablonski Diagram

Alexander Jablonski  
(1898-1980)

Jean Perrin  
(1870-1942)

::BASICS OF FLUORESCENCE LIFETIME

The diagram design is a (C) by Michael W. Davidson and The Florida State

# Fluorescence properties

## Spectra

Stoke's shift

Mirror image rule

## Fluorescence brightness

Quantum yield – number of emitted photons relative to the numbers of absorbed photons

$$Q = \frac{\Gamma}{\Gamma + k_{nr}}$$

## Fluorescence lifetime

# Fluorescence Lifetime Definition

$\tau$

## The fluorescence lifetime

[lifetime of the excited state] is defined by the average time the molecule spend in the excited state prior to return to the ground state.

1 
$$\tau = \frac{1}{\Gamma + k_{nr}}$$

2 
$$n(t) = n_0 \exp(-t/\tau)$$

3 
$$I(t) = I_0 \exp(-t/\tau)$$

# Multi-exponential decays

## Multiple components

In case of two- and more components with different lifetime are present, the decay will become **multiexponential**.

1

$$I(t) = \alpha_1 e^{-t/\tau_1} + \alpha_2 e^{-t/\tau_2}$$

$\alpha$  – pre-exponential factor

2

$$I(t) = \sum_i \alpha_i e^{-t/\tau_i}$$

## Measurement

Following the excitation, the decay time is calculated from the slope of a plot of  **$\log I(t)$**  versus  **$t$** .

Time- and Frequency Domains

# Frequency domain measurements

With the modulated light serving as a source for excitation, the emission is delayed in time.

$$\tan \varphi = \omega \tau_{\varphi}$$

# Time-domain measurements

Analog  
vs  
Counting

---

The **3** steps:  
Collection  
Waveform restoration  
Calculation

# Summary

1. The **fluorescence** is a type of **luminescence** – property of compounds to emit light, when excited with different energy carriers.
2. The fluorescence has a number of properties, such as **spectra**, **quantum yield** and **lifetime**, whereas the fluorescence itself is not the only way of releasing the excess of energy (Perrin-Jablonski diagram).
3. Lifetime is a probability process, whereas excited molecules have the same probability of emitting a photon over some period of time – a decay law.
4. The lifetime is well described by exponential decay.
5. The lifetime is measured currently mostly with frequency and time-domain measurement techniques.

## TIME-CORRELATED SINGLE PHOTON COUNTING

# History

192  
6

First experiment of lifetime measurement by Gaviola. Phase fluorometry applied.

198  
4

D. O'Connor and D. Phillips. First monography on TCSPC

TCSPC is used primarily to record fluorescence decay of dye solutions in cuvettes.

- + Amazingly sensitive and accurate technique with excellent time-resolution
- Slow acquisition, single dimension.

The Becker&Hickl Era.

198  
3

SPC-100, the first model of TCSPC board

199  
2

FPGA-based board introduced: the TCSPC on the rise.

199  
2

Introduction of the first multidimensional system. 100 times faster than before!

# The principle

## The task:

to reconstruct the fluorescence decay waveform.

## Solution:

repetitive excitation and memory channels.

## Building from the scratch

- Detect the time of photon arrival in a high-precision manner.
- Maintain low level of deviation.
  - Assign each photon to the corresponding memory channel

# The instrumentation: Light sources

## The light source:

# The instruments in reality

## The Board

## Detectors

::TCSPC

# The real lab

::TCSPC

# The TCSPC characteristics

## Time resolution:

Not limited by the standard Single Electron Response (SER), which limits the resolution of the analog techniques. The TCSPC is rather dependent on the Transit Time Spread (TTR), which varies in the range of 15-400 ps depending on the detector. The resolution of the board is fs per channel.

## Counting efficiency:

$$SNR = \sqrt{N}$$

Near-ideal efficiency

## Sensitivity:

$$S = \frac{(R_d * N/T)^{1/2}}{Q}$$

$R_d$  – dark count rate ( $300 \text{ s}^{-1}$ ),  
 $N$ – number of time channels (256)  
 $T$  – measurement time (100s)  
 $Q$  – quantum efficiency (0.1)

$S=280 \text{ photons/s}$

## Count rate:

Pile-up problem and insignificance for the TCSPC. Possible rates:

$5 \times 10^6/\text{s}$

## Acquisition time:

More than 300.000 in 100 ms.

# Summary

1. The **TCSPC** systems were sensitive and precise from the beginning, however, limitation in the light source repetition rate and slow electronics made the acquisition times enormously big.
2. The basic principle of the TCSPC is based on the repetitive excitation, collection of the photons, placing them in the corresponding memory channel and further building of the decay curve.
3. Upon the introduction with the high-repetition rate lasers with ultra-short pulses (Ti:Sapphire) the main limitation factor of the system is the detector with the transit time spread around 300ps, and time uncertainty introduced by afterpulses, dark noise, amplitude jitter and color sensitivity.
4. The limitations of the PMTs are addressed by the electronics of TCSPC with the noise and jitter filtered and corrected by the CFDs, high-precision working TAC and ADCs.
5. Currently additional modalities are introduced to the market: multidimensional TCSPC allows to correlate lifetime with other parameters, such as spatial coordinates (scanning) and spectrum-resolved.

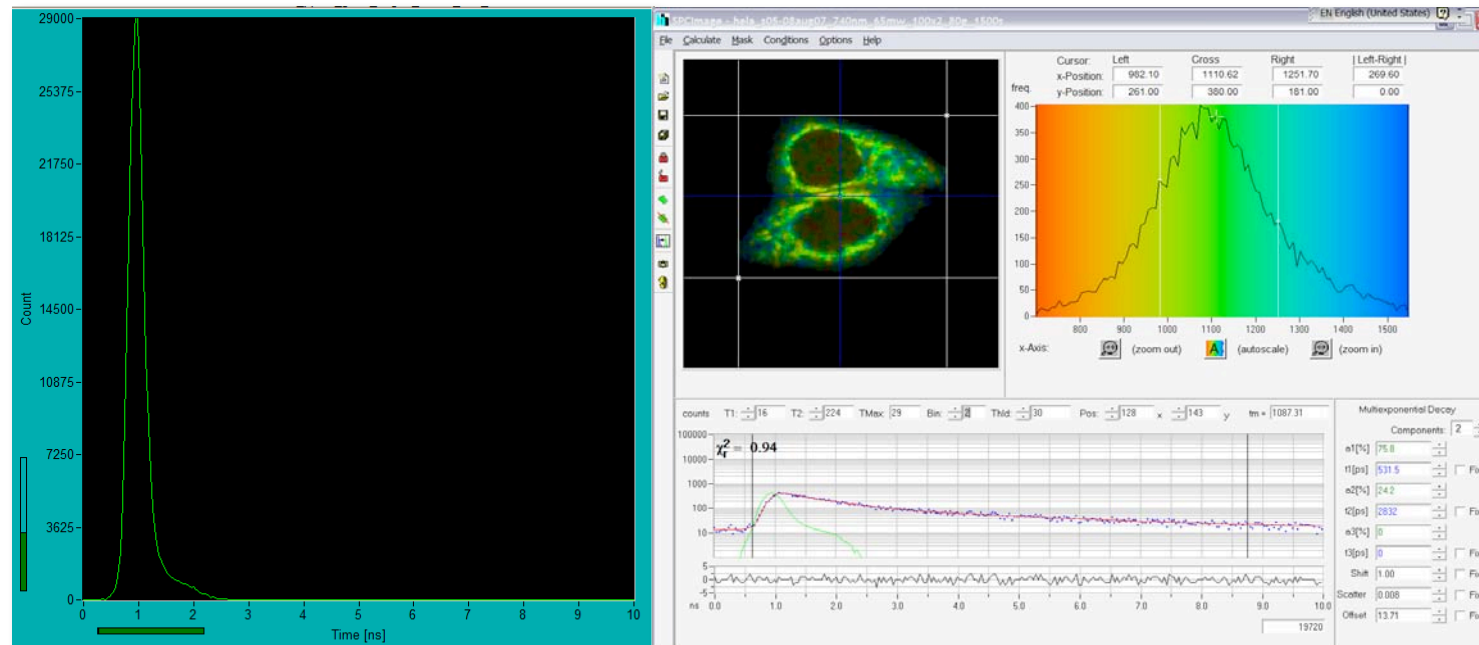

DATA ANALYSIS

# Got the data. What next?

- Development of the decay model.
- Calculation of the Instrument Response Function.
- Convolution of the model with IRF
- Fitting of the resulting model with the data.

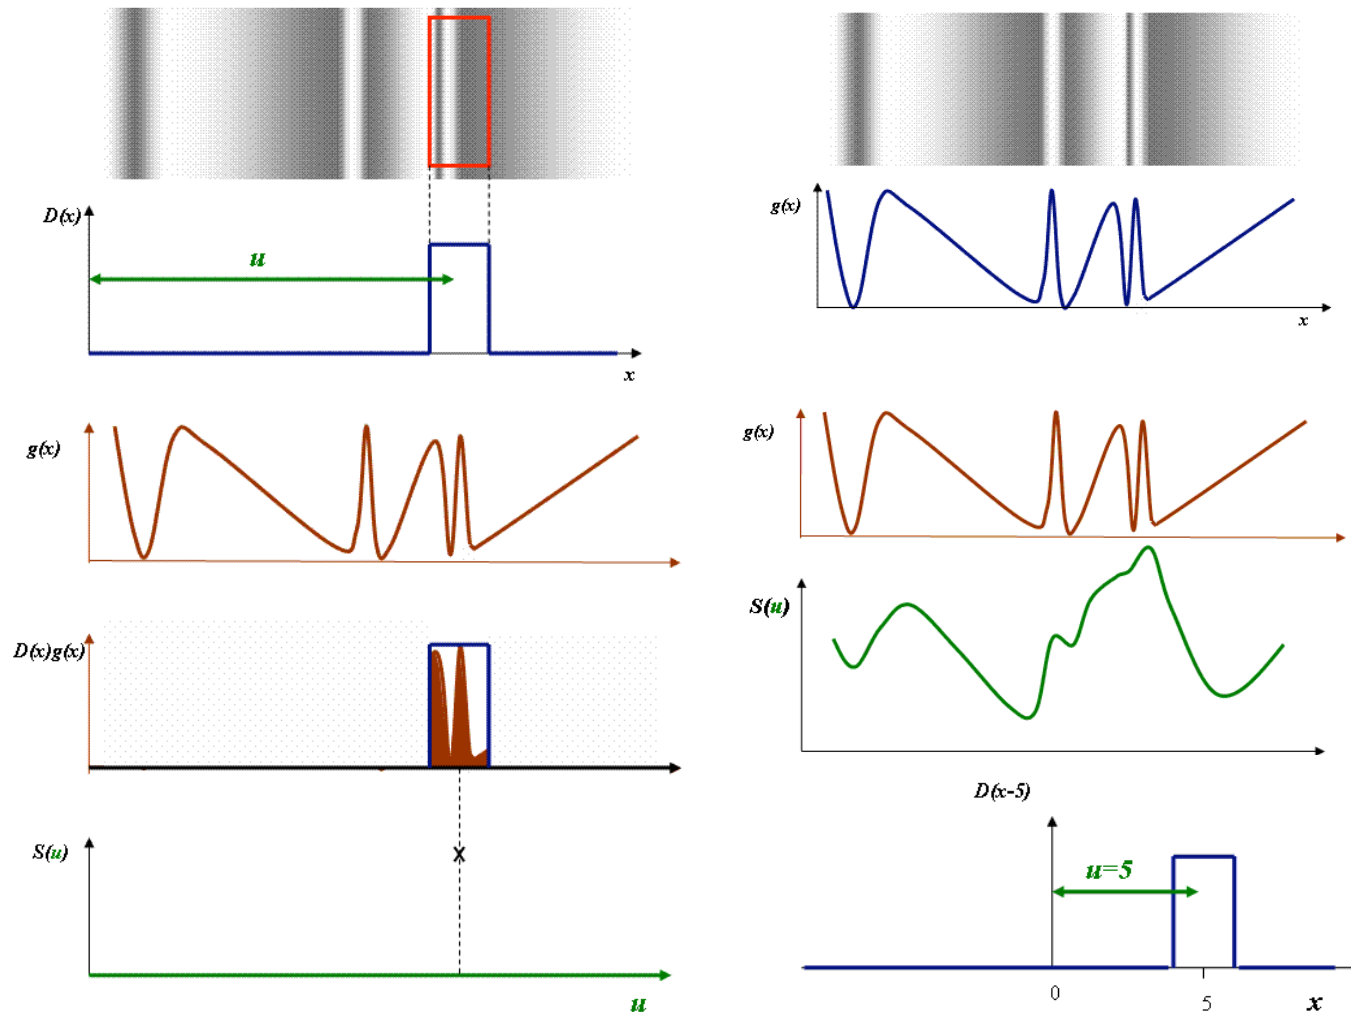

# The Instrument Response Function

## Measurement:

- Scattering for single-photon excitation
- Second Harmonic Generation for 2-photon excitation.

# The Instrument Response Function

$$f(x) = g(x) \oplus h(x)$$

$$S(u) = \int g(x)D(x-u)dx$$

# Deriving the model function

$$I_0 + \sum_{i=1}^n a_i (\exp(-t/\tau_i))$$

## Data set for analysis

Instrument response (IRF)

+  $N(t_k)$  Measured photons  
distribution over  $t$

+  $Nc(t_k)$  Calculated decay

+ Residuals

$$I(t) = \int_{-\infty}^{\infty} L(t_k) \left\{ I_0 + \sum_{i=1}^n a_i (\exp(-t/\tau_i)) \right\} dt$$

Convolution improves the temporal resolution

# Fitting the data

## Standard deviation

$$\sigma_k = [N(t_k)]^{1/2}$$

## Goodness-of-fit parameter calculation

$$\chi^2 = \sum_{k=1}^n \frac{[N(t_k) - N_c(t_k)]^2}{N(t_k)}$$

## Reduced goodness-of-fit

$$\chi_R^2 = \frac{\chi^2}{n - p}$$

Where

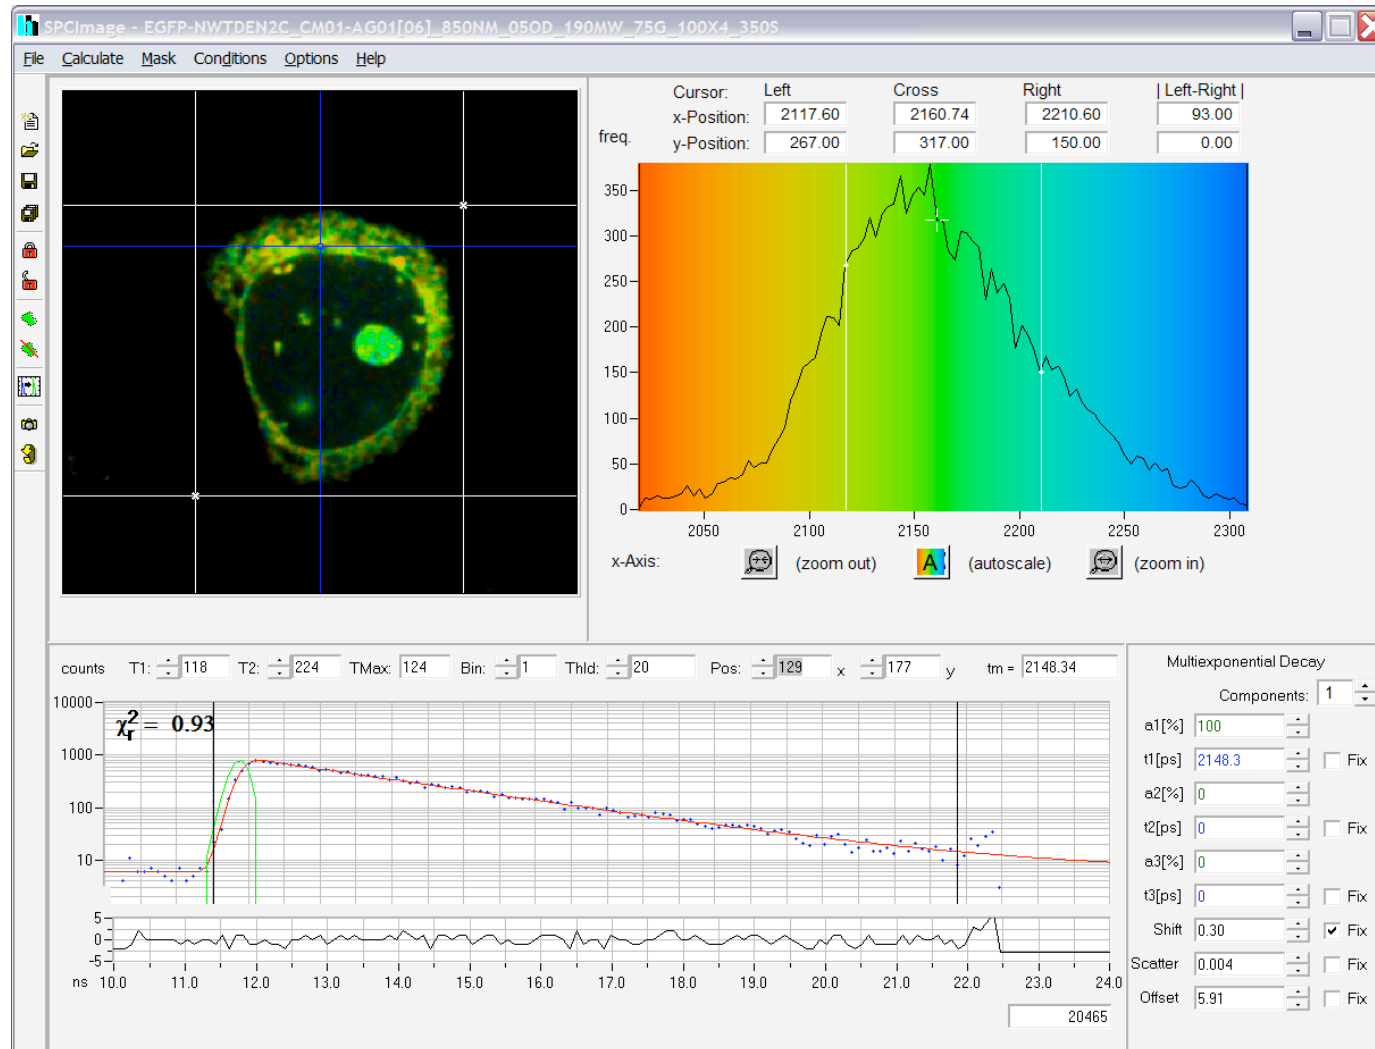

n- number of time channels,

p – number of parameters

Levenberg-Marquardt Algorithm.

# Color-Coding

:::DATA ANALYSIS

# Summary

1. The data obtained is convolved by the Instrument Response Function. To restore the original values and increase the temporal resolution a separately measured Instrument Response Function is convolved with the model function.
2. Upon convolution the temporal resolution increases almost x10.
3. After the convolution the fitting procedure is applied to let the model function follow the measured decay.

THE APPLICABILITY OF FLIM

# FLIM and the others

- Atomic Force Microscopy
  - Limited penetration depth
  - Ability to perform the live objects imaging
- Electron Microscopy
  - Good penetration depth
  - Pre-processing required
- Fluorescence Microscopy
  - Dependence on the excitation and emission wavelengths
  - Dependence on the intensity of the excitation
  - Dependence on the sample concentration

R. Tsien, "Imaging Imaging Future", Nature 2003.

# Experimental time window

The 150fs resolution by the current generation lasers

Picoseconds resolution by the detectors

Confocal/2-photon microscopy: excitation volume of 0.1fL

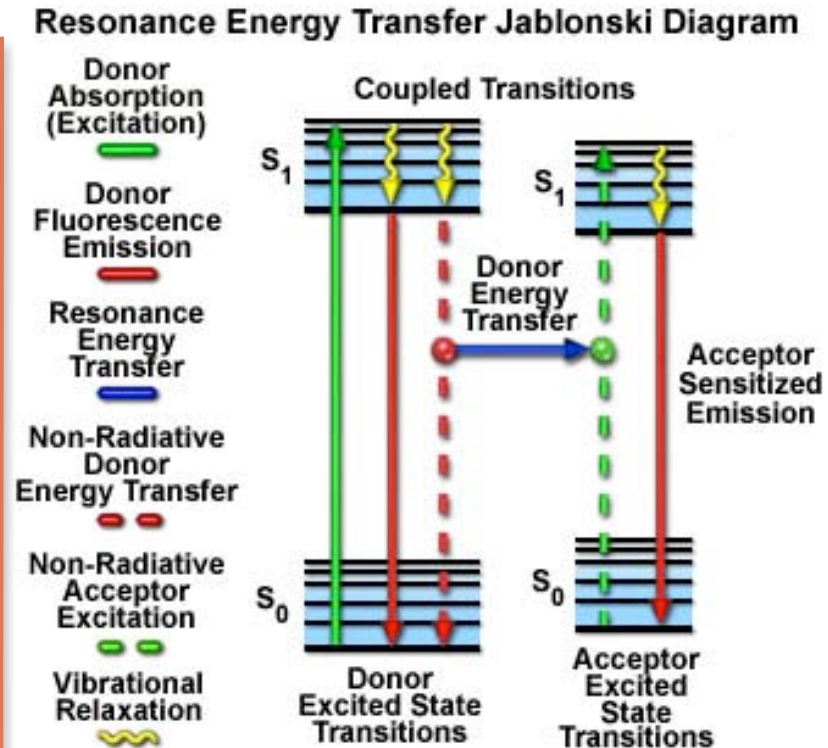

Spatial resolution: 200-300 nm.

# FLIM probing / Quenching

- a. Close proximity: Static  
In the close distance. Intramolecular reactions.
- c. Collisional: Dynamic quenching  
In solutions. Intermolecular reactions.
- b. Distant: Non-radiate transfer of energy At the distance of 2-10 nm.  
Non-radiative energy transfer.  
Intermolecular

## Conditions for FRET to happen

1. **Spectral overlap** between donor emission and acceptor excitation.
2. **Relative orientation** of the donor and acceptor transition dipoles.
3. **Necessary level** of the donor quantum yield.

# FLIM probing / Quenching

## Rate calculation

$$k_T = \frac{Q_D \kappa^2}{\tau_D r^6} \left( \frac{9000 \ln 10}{128 \pi N n^4} \right) \int_0^\infty F_D(\lambda) \varepsilon(\lambda) \lambda^4 d\lambda$$

$\tau_D$  – is the lifetime of the **D** w/o **A**  
 **$Q_D$**  – quantum efficiency of the donor,  
 $\kappa$  – orientation factor,  $r$  – distance  
 between molecules,  $F_D$  – normalized  
 fluorescence intensity,  $\varepsilon$  - extinction  
 coefficient

$$k_T = \frac{1}{\tau} \left( \frac{R_0}{r} \right)^6 \quad \mathbf{R_0 - Forster distance}$$

$$E = \frac{R_0^6}{R_0^6 + r^6} = \frac{1}{1 + (r/R_0)^6}$$

# The FLIM-FRET saga

## Interactions

- FRET efficiency of fluorophores pairs
- Caspases activity
- Detection of apoptosis
- Proteases activity

## Conformation

S

Protein-protein interactions

Dimers formations

Contraction of cells

Detection of clustered distribution

Genotyping (via PCR)

Location-specific activity of molecules

DNA-protein interactions

Molecules

Relative o

## Disruption

# Summary

1. The applicability of FLIM is explained with the time scale of the average lifetime comparable with the dynamical processes in the environment.
2. Combination of FLIM with RET provides with the indirect “Spectroscopic Ruler”.
3. The FLIM/RET combination provides with a rich toolkit, whereas the imagination is the limit.

THE APPLICATIONS :: VIRAL DIAGNOSTICS BY MEANS OF FLIM/FRET

# Enterovirus

- Hand-foot-and-mouth disease •
  - Encephalitis •
  - Aseptic meningitis •
  - Pulmonary oedema •
- Poliomyelitis-like paralysis •

# Enterovirus

## **PATHOLOGY**

Associated with:

- Hand-foot-and-mouth disease •
- Encephalitis •
- Aseptic meningitis •
- Pulmonary oedema •
- Poliomyelitis-like paralysis •

## **RECENT OUTBREAKS**

Taiwan, 1998  
the biggest outbreak,  
**129106** infected  
**78** dead

Singapore, 2000  
**thousands** infected  
**4** dead

APPLICATIONS I

# Potential applications

- The 2Apro microscopy based assay has a high efficiency in detecting the enteroviral infection. High specificity.
- Infection cycle of many viruses depend on the maturation cleavage. The proposed assay may help to trace the activity of these viruses during infection.
- The 2A<sup>pro</sup> is specific for all *Picornaviridae*. Thus detection of these viruses is possible with the given assay. The medical treatment of the patients with these infections doesn't differ in case of different species, thus the method has a potential for clinical diagnostics.
- Specificity of the proteases is observed for some other viruses, such as HIV, which makes the assay a potential method for this virus also.

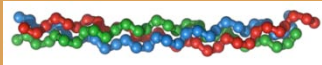

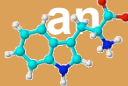

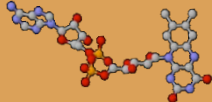

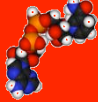

THE APPLICATIONS :: AUTOFLUORESCENCE IMAGING

# Autofluorescence

The main sources of light in cells:

	Collagen 	Tryptophan 	Flavins 	NADH 
Location	Connective tissues Extracellular matrix Inside certain cells Main component : • Cartilage • Fascia • Ligaments	Basic component of cells	Basic component of cells	Basic component of cells
Observation	• Second Harmonic Generation • Fluorescence	Fluorescence	Fluorescence	• Fluorescence • Fluorescence Lifetime

# NADH – The battery of life

ATP (Adenosine triphosphate) is the main energy source in cells, enabling all the synthesis and other endergonic reactions, as well as increasing the rate of exergonic.

**NADH** (Reduced nicotinamide adenine diphosphate) is a part of the oxidative phosphorylation pathway, which is the most efficient way to produce ATP in aerobic cells.

# NADH – The 2 “forms of existence”

The NADH, involved in the first step of the oxidative phosphorylation, serves as an electron donor, creating the intermembrane potential.

The potential is used by ATP synthase to phosphorylate ADP and AMP.

# 2

When involved in the ATP production, the molecules bind to enzymes (bound pool, mainly located in mitochondria).

Otherwise, distributed as single molecules in cytosole (free pool).

**THE RATIO BETWEEN TWO POOLS ILLUSTRATE THE METABOLICAL ACTIVITY OF THE CELLS.**

# NADH – Detecting and distinguishing

The spectra:  
Difference between the peaks for free (A) and bound forms (B, C) are just 10-20 nm, whereas the spectrum width ~150 nm wide.

**Low Sensitivity**

The **lifetime**:  
Difference between the peaks for free and bound forms are well separated: 400 ps vs ~2800 ps.

**Excellent Sensitivity**

# The MOL autofluorescence profile

## The influence of aging on the NADH fluorescence lifetime

V. Ghukasyan<sup>1</sup>, CTChen<sup>2</sup>, YHWei<sup>2</sup>, and FJKao<sup>1</sup>  
Institute of Biophotonics Engineering,  
National Yang-Ming University

In progress

Averaged data from 5 samples from each donor.

# The experimental conditions

Measurements taken from HeLa, grown on cover slides, coated with FBS.

Initial concentration:  $1 \times 10^4$  /ml. First measurement taken after 12 hours upon placing on the cover slide with further measurements taken every 24 hours.

1 hour before the measurement the cover slides were placed in a chamber and 1 ml of fresh DMEM (5% FBS) added and incubated.

---

Objective: 100x, NA=1.4, Plan ApoChromat  
Laser operated at 76MHz at 740 nm (2-photon)  
Laser power measured at the focal plane: 4-5 mW  
Image acquisition: 1500 s.

---

This measurement is a part of overall studies aimed to characterize the NADH lifetime dynamics.

# Results

The first lifetime component is gradually decreasing as the cell culture density is increasing.

The  $\tau_1$  dynamics

# Precautions/controls

The first lifetime component is gradually decreasing as the cell culture density is increasing.

An Artifact?

Possible causes/controls:

a. Limited oxygen supply

➤ Should result in changed pre-exponential factors ratio. (see next slides)

b. Limitation of nutrition elements:

➤ For the purpose of the experiments the cells, grown on cover slides, were replaced to the chamber and covered with the fresh media with further incubation for 10 minutes.

# Results

The long lifetime component  $\tau_2$  doesn't exhibit any distinguishable dynamics.

APPLICATIONS II

# Results

No distinguishable trends in pre-exponential factors.

# Results

Day 1

Day 2

Day 3

Day 4

APPLICATIONS II

# Resume

Among the currently available systems, FLIM, especially in combination with RET, provides with unsurpassed possibilities at high temporal and spatial resolution. This is especially true in case of live cells observation.

See you there...

Thank you!
